

# Package: SMM (via r-universe)

September 10, 2024

**Type** Package

**Title** Simulation and Estimation of Multi-State Discrete-Time  
Semi-Markov and Markov Models

**Version** 1.0.2

**Date** 2020-01-24

**Depends** seqinr, DiscreteWeibull

**Author** Vlad Stefan Barbu, Caroline Berard, Dominique Cellier, Mathilde  
Sautreuil and Nicolas Vergne

**Maintainer** Nicolas Vergne <nicolas.vergne@univ-rouen.fr>

**Description** Performs parametric and non-parametric estimation and simulation for multi-state discrete-time semi-Markov processes. For the parametric estimation, several discrete distributions are considered for the sojourn times: Uniform, Geometric, Poisson, Discrete Weibull and Negative Binomial. The non-parametric estimation concerns the sojourn time distributions, where no assumptions are done on the shape of distributions. Moreover, the estimation can be done on the basis of one or several sample paths, with or without censoring at the beginning or/and at the end of the sample paths. The implemented methods are described in Barbu, V.S., Limnios, N. (2008) <doi:10.1007/978-0-387-73173-5>, Barbu, V.S., Limnios, N. (2008) <doi:10.1080/10485250701261913> and Trevezas, S., Limnios, N. (2011) <doi:10.1080/10485252.2011.555543>. Estimation and simulation of discrete-time k-th order Markov chains are also considered.

SMM-package

*SMM : Semi-Markov and Markov Models*

---

## Description

This package performs parametric and non-parametric estimation and simulation for multi-state discrete-time semi-Markov processes. For the parametric estimation, several discrete distributions are considered for the sojourn times: Uniform, Geometric, Poisson, Discrete Weibull and Negative Binomial. The non-parametric estimation concerns the sojourn time distributions, where no assumptions are done on the shape of distributions. Moreover, the estimation can be done on the basis of one or several sample paths, with or without censoring at the beginning or/and at the end of the sample paths. Estimation and simulation of discrete-time k-th order Markov chains are also considered.

## Details

This R package provides the following functions: `estimSM`, `simulSM`, `LoglikelihoodSM`, `AIC_SM`, `BIC_SM`, `InitialLawSM`, `estimMk`, `simulMk`, `LoglikelihoodMK`, `AIC_Mk`, `BIC_Mk` and `InitialLawMk`.

AIC\_Mk

*AIC (Markov model)*

---

## Description

AIC

## Usage

AIC\_Mk(seq, E, mu, Ptrans, k)

**Arguments**

seq	List of sequence(s)
E	Vector of state space
mu	Vector of initial distribution
Ptrans	Matrix of transition probabilities
k	Order of Markov model

**Details**

$AIC(M) = -2 * \log L + 2 * M$ , where L is the log-likelihood, M is the number of parameters of the model.

**Value**

AIC                    List: value of AIC for each sequence

**Author(s)**

AIC\_SM

*AIC (semi-Markov model)*

---

### Description

AIC

### Usage

```
AIC_SM(seq, E, mu, Ptrans, distr = "NP", param = NULL, laws = NULL, TypeSojournTime)
```

### Arguments

seq	List of sequence(s)
E	Vector of state space of length S
mu	Vector of initial distribution
Ptrans	Matrix of transition probabilities of the embedded Markov chain $J = (J_m)_m$
distr	- "NP" for nonparametric case, laws have to be used, param is useless - Matrix of distributions of size SxS if TypeSojournTime is equal to "fj"; - Vector of distributions of size S if TypeSojournTime is equal to "fi" or "fj"; - A distribution if TypeSojournTime is equal to "f". The distributions to be used in distr must be one of "uniform", "geom", "pois", "dweibull", "nbinom".
param	- Useless if distr = "NP" - Array of distribution parameters of size SxSx2 (2 corresponds to the maximal number of distribution parameters) if TypeSojournTime is equal to "fj"; - Matrix of distribution parameters of size Sx2 if TypeSojournTime is equal to "fi" or "fj"; - Vector of distribution parameters of length 2 if TypeSojournTime is equal to "f".
laws	- Useless if distr $\neq$ "NP" - Array of size SxSxKmax if TypeSojournTime is equal to "fj"; - Matrix of size SxKmax if TypeSojournTime is equal to "fi" or "fj"; - Vector of length Kmax if the TypeSojournTime is equal to "f". Kmax is the maximum length of the sojourn times.
TypeSojournTime	Character: "fj", "fi", "fj", "f"

**Details**

$AIC(M) = -2 * \log L + 2 * M$ , where L is the log-likelihood, M is the number of parameters of the model.

**Value**

estimMk

*Estimation of a k-th order Markov chain*

---

## Description

Estimation of the transition matrix and initial law of a k-th order Markov chain starting from one or several sequences.

## Usage

```
estimMk(file = NULL, seq, E, k)
```

```
estimMk(file, seq = NULL, E, k)
```

## Arguments

file	Path of the file in fasta format which contains the sequences from which to estimate
seq	List of sequence(s)
E	Vector of state space
k	Order of the Markov chain

## Details

Let  $X_1, X_2, \dots, X_n$  be a trajectory of length  $n$  of the Markov chain  $X = (X_m)_{m \in \mathbb{N}}$  of order  $k=1$  with transition matrix  $Ptrans(i, j) = P(X_{m+1} = j | X_m = i)$ . The estimation of the transition matrix is  $\widehat{Ptrans}(i, j) = N_{ij}/N_i$ , where  $N_{ij}$  is the number of transitions from state  $i$  to state  $j$  and  $N_i$  is the number of transition from state  $i$  to any state. For  $k > 1$  we have similar expressions.

The initial distribution of a k-th order Markov chain is defined as  $init = P(X_1 = i)$ . An estimation of the initial law for a first order Markov chain is assumed to be the estimation of the stationary law. If the order of the Markov is greater than 1, then an estimation of the initial law is  $init = N_i/N$ , where  $N_i$  is the number occurrences of state i in the sequences and  $N$  is the sum of the sequence lengths.

### Value

estimMk returns the transition probability matrix of size  $(S^k) \times S$  (with  $S = \text{length}(E)$ ) and the initial law of size  $S$  estimated from the sequence(s) with a Markov model of order k.

The transition matrix is always given in the alphabetical and numerical order, even if the vector of state space is not given in this order.

```

**Description**

Estimation of a semi-Markov chain starting from one or several sequences. This estimation can be parametric or non-parametric, non-censored, censored at the beginning and/or at the end of the sequence, with one or several trajectories. Several parametric distributions are considered (Uniform, Geometric, Poisson, Discrete Weibull and Negative Binomial).

**Usage**

```
# parametric case
estimSM(file = NULL, seq, E, TypeSojournTime = "fij", distr, cens.end = 0,
cens.beg = 0)

estimSM(file, seq = NULL, E, TypeSojournTime = "fij", distr, cens.end = 0,
cens.beg = 0)

# non-parametric case
estimSM(file = NULL, seq, E, TypeSojournTime = "fij", distr = "NP", cens.end = 0,
cens.beg = 0)

estimSM(file, seq = NULL, E, TypeSojournTime = "fij", distr = "NP", cens.end = 0,
cens.beg = 0)
```

**Arguments**

file	Path of the file in fasta format which contains the sequences from which to estimate
seq	List of the sequence(s)
E	Vector of state space of length S
TypeSojournTime	Character: "fij", "fi", "fj", "f" (for more explanations, see Details)
distr	- "NP" for nonparametric case, laws have to be used, param is useless - Matrix of distributions of size SxS if TypeSojournTime is equal to "fij"; - Vector of distributions of size S if TypeSojournTime is equal to "fi" or "fj"; - A distribution if TypeSojournTime is equal to "f". The distributions to be used in distr must be one of "uniform", "geom", "pois", "dweibull", "nbinom".
cens.beg	Type of censoring at the beginning of sample paths; 1 (if the first sojourn time is censored) or 0 (if not). All the sequences must be censored in the same way.
cens.end	Type of censoring at the end of sample paths; 1 (if the last sojourn time is censored) or 0 (if not). All the sequences must be censored in the same way.

**Details**

This function estimates a semi-Markov model in parametric and non-parametric case, taking into account the type of sojourn time and the censoring described in references. The non-parametric estimation concerns sojourn time distributions defined by the user. For the parametric estimation, several discrete distributions are considered (see below).

The difference between the Markov model and the semi-Markov model concerns the modelisation of the sojourn time. With a Markov chain, the sojourn time distribution is modeled by a Geometric distribution (in discrete time). With a semi-Markov chain, the sojourn time can be any arbitrary distribution. In this package, the available distribution for a semi-Markov model are :

- Uniform:  $f(x) = 1/n$  for  $a \leq x \leq b$ , with  $n = b - a + 1$

- Geometric:  $f(x) = \theta(1 - \theta)^x$  for  $x = 0, 1, 2, \dots, n$ ,  $0 < \theta \leq 1$ , with  $n > 0$  and  $\theta$  is the probability of success
- Poisson:  $f(x) = (\lambda^x \exp(-\lambda))/x!$  for  $x = 0, 1, 2, \dots, n$ , with  $n > 0$  and  $\lambda > 0$
- Discrete Weibull of type 1:  $f(x) = q^{(x-1)^\beta} - q^{x^\beta}$ ,  $x = 1, 2, 3, \dots, n$ , with  $n > 0$ ,  $q$  is the first parameter and  $\beta$  is the second parameter
- Negative binomial:  $f(x) = \Gamma(x+\alpha)/(\Gamma(\alpha)x!)(\alpha/(\alpha+\mu))^\alpha(\mu/(\alpha+\mu))^x$ , for  $x = 0, 1, 2, \dots, n$ ,  $n > 0$ ,  $\Gamma$  is the Gamma function,  $\alpha$  is the parameter of overdispersion and  $\mu$  is the mean
- Non-parametric

We define :

- the semi-Markov kernel  $q_{ij}(k) = P(J_{m+1} = j, T_{m+1} - T_m = k | J_m = i)$ ;
- the transition matrix  $(Ptrans(i, j))_{i,j} \in E$  of the embedded Markov chain  $J = (J_m)_m$ ,  $Ptrans(i, j) = P(J_{m+1} = j | J_m = i)$ ;
- the initial distribution  $init = P(J_1 = i) = P(Y_1 = i)$ ;
- the conditional sojourn time distributions  $(f_{ij}(k))_{i,j} \in E$ ,  $k \in N$ ,  $f_{ij}(k) = P(T_{m+1} - T_m = k | J_m = i, J_{m+1} = j)$ ,  $f$  is specified by the argument "param" in the parametric case and by "laws" in the non-parametric case.

The estimation of the transition matrix of the embedded Markov chain is  $\widehat{Ptrans}(i, j) = N_{ij}/N_i$ .

The estimation of the initial law is the limit law if the number of sequences is equal to 1, else the estimation of the initial law is  $init = N_i^l/N^l$ , where  $N_i^l$  is the number of times the state  $i$  appears in all the sequences and  $N^l$  is the size of sequences.

In the parametric case, the distribution of sojourn time is calculated with the estimated parameters.

Note that  $q_{ij}(k) = Ptrans(i, j) * f_{ij}(k)$  in the general case (depending on the present state and on the next state). For particular cases, we replace  $f_{ij}(k)$  by  $f_i(k)$  (depending on the present state "fi."),  $f_{.j}(k)$  (depending on the next state "f.j") and  $f_{..}(k)$  (depending neither on the present state nor on the next state "f").

In this package we can choose different types of sojourn time. Four options are available for the sojourn times:

- depending on the present state and on the next state ("fij");
- depending only on the present state ("fi");
- depending only on the next state ("fj");
- depending neither on the current, nor on the next state ("f").

If TypeSojournTime is equal to "fij", distr is a matrix (SxS) (e.g., if the row 1 of the 2nd column is "pois", that is to say we go from the first state to the second state following a Poisson distribution). If TypeSojournTime is equal to "fi" or "fj", distr must be a vector (e.g., if the first element of vector is "geom", that is to say we go from the first state to any state according to a Geometric distribution). If TypeSojournTime is equal to "f", distr must be one of "uniform", "geom", "pois", "dweibull", "nbinom" (e.g., if distr is equal to "nbinom", that is to say that the sojourn times when going from any state to any state follows a Negative Binomial distribution). For the non-parametric case, distr is equal to "NP" whatever type of sojourn time given.

If the sequence is censored at the beginning and at the end, cens.beg must be equal to 1 and cens.end must be equal to 1 too. All the sequences must be censored in the same way.

At any use of the function, a file in .txt format is created. This file contains the output of the function.

**Value**

init	Vector of initial distribution
Ptrans	Matrix of transition probabilities of the embedded Markov chain $J = (J_m)_m$ of size $S \times S$
param	- Useless if <code>distr = "NP"</code> - Array of distribution parameters of size $S \times S \times 2$ (2 corresponds to the maximal number of distribution parameters) if <code>TypeSojournTime</code> is equal to "fj"; - Matrix of distribution parameters of size $S \times 2$ if <code>TypeSojournTime</code> is equal to "fi" or "fj"; - Vector of distribution parameters of length 2 if <code>TypeSojournTime</code> is equal to "f".
laws	- Useless if <code>distr ≠ "NP"</code> - Array of size $S \times S \times K_{max}$ if <code>TypeSojournTime</code> is equal to "fj"; - Matrix of size $S \times K_{max}$ if <code>TypeSojournTime</code> is equal to "fi" or "fj"; - Vector of length $K_{max}$ if the <code>TypeSojournTime</code> is equal to "f". $K_{max}$ is the maximum length of the sojourn times.
q	Array of size $S \times S \times K_{max}$ with the estimated semi-Markov kernel

InitialLawMk                      *Estimation of the initial law (Markov model)*

---

### Description

For order 1, estimation of initial law by computing the stationary law of the Markov chain.

For order greater than 1, estimation of initial law by computing the state frequencies.

### Usage

```
InitialLawMk(E, seq, Ptrans, k)
```

### Arguments

E	Vector of state space
seq	List of sequence(s)
Ptrans	Matrix of transition probabilities of size $(S^k) \times S$ , with $S = \text{length}(E)$
k	Order of the Markov chain

### Value

init	Vector of the initial law
------	---------------------------

### Author(s)

---

InitialLawSM

*Estimation of the initial law (semi-Markov model)*

---

**Description**

For one sequence, estimation of the initial law by computing the limit law of the semi-Markovian chain.

For several sequences, estimation of the initial law by computing the first state frequencies.

**Usage**

```
InitialLawSM(E, seq, q)
```

**Arguments**

E	Vector of state space
seq	List of sequence(s)
q	Array of size $S \times S \times K_{\max}$ with the semi-Markov kernel ( $S = \text{length}(E)$ )

**Value**

init	Vector of the initial distribution

LoglikelihoodSM

*Loglikelihood (semi-Markov model)*

---

## Description

Computation of the loglikelihood starting from sequence(s), alphabet, initial distribution, transition matrix and type of sojourn times

## Usage

```

## parametric case
LoglikelihoodSM(seq, E, mu, Ptrans, distr, param, laws = NULL, TypeSojournTime)
## non-parametric case
LoglikelihoodSM(seq, E, mu, Ptrans, distr, param = NULL, laws, TypeSojournTime)

```

## Arguments

seq	List of sequence(s)
E	Vector of state space
mu	Vector of initial distribution of length S
Ptrans	Matrix of transition probabilities of the embedded Markov chain $J = (J_m)_m$ of size SxS
distr	- "NP" for nonparametric case, laws have to be used, param is useless - Matrix of distributions of size SxS if TypeSojournTime is equal to "fj"; - Vector of distributions of size S if TypeSojournTime is equal to "fi" or "fj";

- A distribution if TypeSojournTime is equal to "f".  
The distributions to be used in distr must be one of "uniform", "geom", "pois", "dweibull", "nbinom".

param	<ul style="list-style-type: none"> <li>- Useless if distr = "NP"</li> <li>- Array of distribution parameters of size SxSx2 (2 corresponds to the maximal number of distribution parameters) if TypeSojournTime is equal to "fj";</li> <li>- Matrix of distribution parameters of size Sx2 if TypeSojournTime is equal to "fi" or "fj";</li> <li>- Vector of distribution parameters of length 2 if TypeSojournTime is equal to "f".</li> </ul>
laws	<ul style="list-style-type: none"> <li>- Useless if distr <math>\neq</math> "NP"</li> <li>- Array of size SxSxKmax if TypeSojournTime is equal to "fj";</li> <li>- Matrix of size SxKmax if TypeSojournTime is equal to "fi" or "fj";</li> <li>- Vector of length Kmax if the TypeSojournTime is equal to "f".</li> </ul> <p>Kmax is the maximum length of the sojourn times.</p>
TypeSojournTime	Character: "fj", "fi", "fj", "f" (for more explanations, see Details)

## Details

In this package we can choose different types of sojourn time. Four options are available for the sojourn times:

- depending on the present state and on the next state ("fj");
- depending only on the present state ("fi");
- depending only on the next state ("fj");
- depending neither on the current, nor on the next state ("f").

## Value

L	Value of loglikelihood for each sequence
Kmax	The maximal observed sojourn time

simulMk

*Simulation of a k-th order Markov chain*

---

### Description

Simulation of a k-th order Markov chain starting from a transition matrix and an initial distribution.

### Usage

```
simulMk(E, nbSeq, lengthSeq, Ptrans, init, k, File.out = NULL)
```

### Arguments

E	Vector of state space
nbSeq	Number of simulated sequences
lengthSeq	Vector of size nbSeq containing the lengths of each simulated sequence
Ptrans	Matrix of transition probabilities of size $(S^k) \times S$ , with $S = \text{length}(E)$
init	Vector of initial distribution of length S
k	Order of the Markov chain
File.out	Name of the fasta file for saving the sequences. If File.out = NULL, no file is created

**Details**

The sizes of `init` and `Ptrans` depend on `S`, the length of `E`. The rows of the transition matrix sums to 1.

For  $k=1$ , the transition matrix is defined by  $Ptrans(i,j) = P(X_{m+1} = j | X_m = i)$  and the initial distribution is  $init = P(X_1 = i)$ . For  $k > 1$  we have similar expressions.

The first element of `lengthSeq` corresponds to the length of the first sequence and so on.

**Value**

`simulMk` returns a list of sequences of size `lengthSeq` simulated with a  $k$ -th order Markov chain of parameters `init` and `Ptrans` with state space `E`.

If the parameter `File.out` is not equal to `NULL`, a file in fasta format containing the sequence(s) will be created.

init = init.distribution, k = k)

### Example 2 ###
# first order model with state space {1,2,3}
E <- c(1,2,3)
S <- length(E)
init.distr <- rep(1/S, 3)
p <- matrix(c(0.3,0.2,0.5,0.1,0.6,0.3,0.2,0.4,0.4), nrow = 3, byrow = TRUE)

# We simulate one sequence of size 100
simulMk(E = E, nbSeq = 1, lengthSeq = 100, Ptrans = p, init = init.distr, k = 1)
```

---

simulSM	<i>Simulation of a semi-Markov chain</i>
---------	--

---

### Description

Simulation of a semi-Markov chain starting from chosen parameters. This simulation can be parametric or non-parametric, non-censored, censored at the beginning and/or at the end of the sequence, with one or several trajectories. Several parametric distributions are considered (Uniform, Geometric, Poisson, Discrete Weibull and Negative Binomial).

### Usage

```
# parametric case
simulSM(E, NbSeq, lengthSeq, TypeSojournTime = "fij", init, Ptrans, distr, param,
laws = NULL, cens.beg = 0, cens.end = 0, File.out = NULL)

# non-parametric case
simulSM(E, NbSeq, lengthSeq, TypeSojournTime = "fij", init, Ptrans, distr = "NP",
param = NULL, laws, cens.beg = 0, cens.end = 0, File.out = NULL)
```

### Arguments

E	Vector of state space
NbSeq	Number of simulated sequences
lengthSeq	Vector containing the lengths of each simulated sequence (the length of sequences can be different, see details)
TypeSojournTime	Character : must be one of "fij", "fi", "fj", "f" (for more explanations, see Details)
init	Vector of initial distribution of length S, with S = length(E)
Ptrans	Matrix of transition probabilities of the embedded Markov chain $J = (J_m)_m$ (The sum of the probabilities on the same row must be equal to 1. According to semi-Markov model, the probability to stay in the same state is assumed to be equal to 0.)
distr	<ul style="list-style-type: none"> <li>- "NP" for nonparametric case, laws have to be used, param is useless</li> <li>- Matrix of distributions of size SxS if TypeSojournTime is equal to "fij";</li> <li>- Vector of distributions of size S if TypeSojournTime is equal to "fi" or "fj";</li> <li>- A distribution if TypeSojournTime is equal to "f".</li> </ul> The distributions to be used in distr must be one of "uniform", "geom", "pois", "dweibull", "nbinom".
param	<ul style="list-style-type: none"> <li>- Useless if distr = "NP"</li> <li>- Array of distribution parameters of size SxSx2 (2 corresponds to the maximal number of distribution parameters) if TypeSojournTime is equal to "fij";</li> <li>- Matrix of distribution parameters of size Sx2 if TypeSojournTime is equal to "fi" or "fj";</li> </ul>

	- Vector of distribution parameters of length 2 if TypeSojournTime is equal to "f".
laws	- Useless if distr $\neq$ "NP" - Array of size SxSxKmax if TypeSojournTime is equal to "fij"; - Matrix of size SxKmax if TypeSojournTime is equal to "fi" or "fj"; - Vector of length Kmax if the TypeSojournTime is equal to "f". Kmax is the maximum length of the sojourn times.
cens.beg	Type of censoring at the beginning of sample paths; 1 (if the first sojourn time is censored) or 0 (if not). All the sequences must be censored in the same way.
cens.end	Type of censoring at the end of sample paths; 1 (if the last sojourn time is censored) or 0 (if not). All the sequences must be censored in the same way.
File.out	Name of fasta file to save the sequences; if File.out = NULL, no file is created.

## Details

This function simulates a semi-Markov model in the parametric and non-parametric case, taking into account the type of sojourn time and the censoring described in references.

The non-parametric simulation concerns sojourn time distributions defined by the user. For the parametric simulation, several discrete distributions are considered (see below).

The difference between the Markov model and the semi-Markov model concerns the modelling of the sojourn time. With a Markov chain, the sojourn time distribution is modeled by a Geometric distribution. With a semi-Markov chain, the sojourn time can be arbitrarily distributed. In this package, the available distribution for a semi-Markov model are:

- Uniform:  $f(x) = 1/n$  for  $a \leq x \leq b$ , with  $n = b - a + 1$
- Geometric:  $f(x) = \theta(1 - \theta)^x$  for  $x = 0, 1, 2, \dots, n$ ,  $0 < \theta \leq 1$ , with  $n > 0$  and  $\theta$  is the probability of success
- Poisson:  $f(x) = (\lambda^x \exp(-\lambda))/x!$  for  $x = 0, 1, 2, \dots, n$ , with  $n > 0$  and  $\lambda > 0$
- Discrete Weibull of type 1:  $f(x) = q^{(x-1)^\beta} - q^{x^\beta}$ ,  $x = 1, 2, 3, \dots, n$ , with  $n > 0$ ,  $q$  is the first parameter and  $\beta$  is the second parameter
- Negative Binomial:  $f(x) = \Gamma(x+\alpha)/(\Gamma(\alpha)x!)(\alpha/(\alpha+\mu))^\alpha(\mu/(\alpha+\mu))^x$ , for  $x = 0, 1, 2, \dots, n$ ,  $n > 0$ ,  $\Gamma$  is the gamma function,  $\alpha$  is the parameter of overdispersion and  $\mu$  is the mean
- Non-parametric

We define :

- the semi-Markov kernel  $q_{ij}(k) = P(J_{m+1} = j, T_{m+1} - T_m = k | J_m = i)$ ;
- the transition matrix  $(Ptrans(i, j))_{i,j} \in E$  of the embedded Markov chain  $J = (J_m)_m$ ,  $Ptrans(i, j) = P(J_{m+1} = j | J_m = i)$ ;
- the initial distribution,  $init = P(J_1 = i) = P(Y_1 = i)$ ;
- the conditional sojourn time distributions  $(f_{ij}(k))_{i,j} \in E$ ,  $k \in N$ ,  $f_{ij}(k) = P(T_{m+1} - T_m = k | J_m = i, J_{m+1} = j)$ ,  $f$  is specified by the argument "param" in the parametric case and by "laws" in the non-parametric case.

In this package we can choose different types of sojourn times. Four options are available for the sojourn times

- depending on the present state and on the next state ("fij");
- depending only on the present state ("fi");
- depending only on the next state ("fj");
- depending neither on the current, nor on the next state ("f").

If TypeSojournTime is equal to "fij", distr is a matrix (SxS) (e.g., if the row 1 of the 2nd column is "pois", that is to say we go from the first state to the second state following a Poisson distribution). If TypeSojournTime is equal to "fi" or "fj", distr must be a vector (e.g., if the first element of vector is "geom", that is to say we go from the first state to any state according to a Geometric distribution). If TypeSojournTime is equal to "f", distr must be one of "uniform", "geom", "pois", "dweibull", "nbinom" (e.g., if distr is equal to "nbinom", that is to say that the sojourn times when going from any state to any state follows a Negative Binomial distribution). For the non-parametric case, distr is equal to "NP" whatever type of sojourn time given.

If the sequence is censored at the beginning and at the end, cens.beg must be equal to 1 and cens.end must be equal to 1 too. All the sequences must be censored in the same way.

Moreover, in the non-parametric case TypeSojournTime is equal to "fij" then laws must be an array of size SxSxKmax. If distr is equal to "NP" and TypeSojournTime is equal to "fi" or "fj" then laws must be a matrix of size SxKmax. If the distr is equal to "NP" and TypeSojournTime is equal to "f" then laws is a vector of length Kmax.

For the simulation of a non-censored sequence, the length of the sequence can be greater than lengthSeq.

### Value

simulSM returns sequences of size lengthSeq or greater

If File.out is not NULL, a fasta file will be created containing the sequences.
